

Gleesons Pub Sales Analytics Dashboard: Business Insights Report

1. Project Overview:

This project involved building a Power BI dashboard to analyse POS sales data from Gleesons, the pub I work in. The pub had sales data available through its POS system, but there was no dashboard or reporting process for reviewing product performance.

The aim was to turn raw POS data into clear insights. The dashboard made it easier to review revenue, profit, product performance, trading patterns, and product decisions without manually checking POS exports.

The original dashboard was built using internal POS data from Gleesons. For privacy reasons, the real data is not included in the GitHub repository.

2. Business Problem:

The main problem was that sales data was available but not being used. Without analytics, it was difficult to understand which products were performing well, and which products were underperforming.

One key question came from the pub's owner, who suspected that Beamish might be taking sales away from Guinness after it was introduced.

This became the main focus of the project:

Was Beamish adding new sales after being introduced, or was it taking sales away from Guinness?

This mattered because Guinness was one of the pub's strongest performing drinks. If Beamish was mainly replacing Guinness sales instead of creating extra sales, then keeping it could weaken overall performance.

3. Dashboard:

The dashboard was created in Power BI using POS transaction data. The data was cleaned using Power Query, and DAX measures were created for key metrics such as total revenue, total profit, profit margin, units sold, transaction count, and average transaction value.

The dashboard included pages for executive summary, product performance, time analysis, staff activity, profitability analysis, and management recommendations.

For the Beamish vs Guinness analysis, the dashboard was used to compare sales after Beamish was introduced. The focus was on product revenue, sales trends, and revenue per pint. This helped show whether Beamish was adding value or simply shifting sales away from Guinness.

4. Core Finding: Beamish vs Guinness:

Beamish was introduced in December 2025. After it was introduced, Guinness sales started to decline.

When the months from December 2025 to May 2026 were reviewed, Guinness sales had dropped by nearly 7%. The revenue gained from Beamish roughly offset the revenue lost from Guinness. This suggested that Beamish was not creating much additional revenue for the pub. Instead, it appeared to be replacing Guinness sales.

The key issue was that Beamish generated around 11% less revenue per pint than Guinness. This meant that when customers chose Beamish instead of Guinness, the pub earned less.

The dashboard showed that Beamish was not acting as a strong additional product. It appeared to be taking sales from a stronger product and replacing them with lower revenue sales.

5. Recommendation:

The main recommendation was to remove Beamish from the pub and protect Guinness as a stronger product.

The reasoning was simple. Guinness was already a strong drink for the pub, while Beamish appeared to reduce Guinness sales without creating enough extra revenue to justify keeping it.

If a new product increases overall sales, it may be worth keeping. In this case, Beamish seemed to substitute existing Guinness sales rather than add meaningful new sales. Since Beamish also generated around 11% less revenue per pint, it was a weaker product to keep in the range.

6. Business Impact:

This project had a practical impact because the analysis supported a real decision in the business.

Beamish was removed from the Gleesons after the dashboard showed that it was taking sales away from Guinness while generating less revenue per pint. The analysis turned what could have been a guess into a clearer data-backed decision.

The dashboard also gave the pub a better way to review sales performance in future. Instead of relying only on POS exports or assumptions, the pub now has a simple reporting structure that can be refreshed with new sales data.

7. Conclusion:

This project showed how basic analytics can support practical decision-making in a small family business. By building a Power BI dashboard, raw POS data was turned into a clear analysis of product performance.
